# Introduction

图:

- Let  $S$  be a set of points in  $\mathbb{R}^2$ . Given an axis-parallel rectangle  $Q$ , a range query retruns all the points of  $S$  that are covered by  $Q$ , namely,  $S \cap Q$
- The definition can be extended to any dimensionality in a straightforward manner

# Introduction

Essentially, this is a two-dimensional partial ordering problem

- 2-d prefix sum
- weighted segment tree、binary indexed tree
- k-d tree
- R tree
- ...

But today I want to introduce range trees to provide a new way to solve this problem

# Introduction

- The 2-dimensional range query is essentially composed of two 1-dimensional sub-queries, one on the x-coordinate of the points and one on the y-coordinate
- In other words, we can only care about one dimension first

# 1-dimensional range tree

**Question:** How to efficiently find all the points between the two boundary points?

# 1-dimensional range tree

- Node
  - size, the external nodes in p's subtree
  - left, point to the left subtree
  - right, point to the right subtree
  - isLeaf, we call the leaves as external nodes, the remaining as inner nodes
- e.g. we illustrate for the interval  $[2, 23]$

# 1-d range query algorithm

## Algorithm 1: 1DRangeQuery( $T, [x_1 : x_2]$ )

```

1 if  $p$  is external node then
2   if  $p$  in range  $[x_1, x_2]$  then
3     return 1
4   else
5     return 0
6   end
7 else if  $[x_1, x_2]$  contains  $p$  then
8   return  $p.size$ 
9 else if  $p$  disjoint from  $[x_1, x_2]$  then
10  return 0
11 return 1DRangeQuery( $T(left), x_1, x_2$ ) + 1DRangeQuery( $T(right), x_1, x_2$ )
  
```

### theorem

1-dimensional range counting queries can be answered in  $O(\log n)$  time and range reporting queries can be answered in  $O(k + \log n)$  time, where  $k$  is the number of values reported.

## ③ 2-dimensional range tree

## ④ Higher dimensional range trees

## ⑤ Can we do better?

## ⑥ Revisiting K-D Tree

## ⑦ Application

## 2-dimensional range tree

- We first build a range tree based on the x-coordinate, and then for each point, we build another range tree based on the y-coordinate.
- Each node has an additional pointer "aux", pointing to the range tree built based on the y-coordinate

## Construction algorithm

- $T(n) = 2 \cdot T(n/2) + O(n)$
- The construction algorithm takes  $O(n \log n)$  time

## 2-d range query algorithm

- Query  $[4 : 19] \times [y_1 : y_2]$

- Similar to the approach in one dimension, start by finding  $v_{split}$
- For points along the path starting from the split that meet the x criteria, query the y-coordinate

## 2-d range query algorithm

### Algorithm 2: 2DRangeQuery( $T, [x_1 : x_2] \times [y_1 : y_2]$ )

```

1  $v_{split} \leftarrow \text{FindSplitNode}(T, x_1, x_2)$ ;
2 if  $v_{split}$  is a leaf then
3   | Check if the point in  $v_{split}$  must be reported.
4 else
5   |  $v \leftarrow lc(v_{split})$ 
6   | while  $v$  is not a leaf do
7     | if  $x_1 \leq \text{value}(v)$  then
8       |   1DRangeQuery( $T_y(rc(v)), [y_1 : y_2]$ )
9       |    $v \leftarrow lc(v)$ 
10      | else
11        |  $v \leftarrow rc(v)$ 
12      | end
13    | end
14    | Check if the point in  $v$  must be reported.
15    | Similarly, follow the patch from  $rc(v_{split})$  to  $x_2$ 
16 end

```

## 2-d range query efficiency

- We search in  $O(\log n)$  associated structures to perform a 1D range query
- The query time is  $O(\log^2 n + k)$ , where  $k$  is the size of the output

### theorem

A set of  $n$  points in the plane can be processed in  $O(n \log n)$  time into a data structure of  $O(n \log n)$  size so that any 2D range query can be answered in  $O(\log^2 n + k)$  time, where  $k$  is the number of answers reported.

Recall that a  $k$ -d tree has  $O(n)$  size and answers queries in  $O(\sqrt{n} + k)$  time

## My own understanding

- It feels like a range tree is very similar to a segment tree
- The range tree is divided by taking the median
- Therefore, some voices on the Internet say that a two-dimensional segment tree is also a two-dimensional range tree

## ① Introduction

## ② 1-dimensional range tree

## ③ 2-dimensional range tree

## ④ Higher dimensional range trees

## ⑤ Can we do better?

## ⑥ Revisiting K-D Tree

## ⑦ Application

# Higher dimensional range trees

A  $d$ -dimensional range tree has a main tree which is a one-dimensional balanced binary tree on the first coordinate, where every node has a pointer to an associated structure that is a  $(d-1)$ -dimensional range tree on the other coordinates.

# Storage

$$S_1(n) = O(n) \quad \text{for all } n$$

$$S_d(1) = O(1) \quad \text{for all } d$$

$$S_d(n) \leq 2 \times S_d(n/2) + S_{d-1}(n) \quad \text{for } d \geq 2$$

- This solves to  $S_d(n) = O(n \log^d n)$

# Query time

- The number of grey nodes  $G_d(n)$  satisfies:

$$G_1(n) = O(\log n) \quad \text{for all } n$$

$$G_d(1) = O(1) \quad \text{for all } d$$

$$G_d(n) \leq 2 \times \log n \times G_{d-1}(n) \quad \text{for } d \geq 2$$

- This solves to  $G_d(n) = O(n \log^d n)$
- In fact, we can also use induction to prove this

# Result

## theorem

A set of  $n$  points in a  $d$ -dimensional space can be processed in  $O(n \log^{d-1} n)$  time into a data structure of  $O(n \log^{d-1} n)$  size so that any  $k$ -D range query can be answered in  $O(\log^d n + k)$  time, where  $k$  is the number of answers reported.

Recall that a  $kd$ -tree has  $O(n)$  size and answers queries in  $O(n^{1-1/d} + k)$  time

## ① Introduction

## ⑦ Application

# Fractional cascading

- We can improve the query time of a 2D range tree from  $O(\log^2 n)$  to  $O(\log n)$  by a technique called **fractional cascading**
- The idea illustrated best by a different query problem:  
Suppose that we have a collection of sets  $S_1 \dots S_m$ , where  $|S_1| = n$  and where  $S_{i+1} \subset S_i$
- We want a data structure that can report for a query number  $x$ , the smaller value greater than equals to  $x$  in all sets  $S_1 \dots S_m$

# Fractional cascading

- Each number in the upper level is connected to the first number in the lower level that is greater than or equal to it.
- e.g. We want to find the first number that greater than 33.

# Fractional cascading

- Now we do "the same" on the associated structures of a 2-dimensional range tree
- Note that on every associated structure, we search with the same values  $y_1$  and  $y_2$
- Replace all associated structures (y trees) with sorted lists
- For every list element (and leaf of the associated structure of the root), store two pointers to the appropriate list elements in the lists of the left child and of the right child

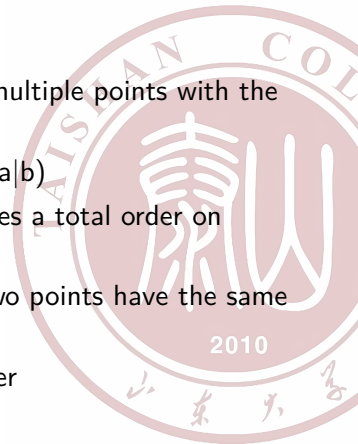

# Result

## theorem

A set of  $n$  points in  $d$ -dimensional space can be preprocessed in  $O(n \log^d n)$  time into a data structure of  $O(n \log^{d-1} n)$  size so that any  $k$ -D range query can be answered in  $O(\log^{d-1} n + k)$  time, where  $k$  is the number of answers reported.

## Degenerate cases

- Both for kd-trees and for range trees we have to take care of multiple points with the same x- or y-coordinate
- We define a composite number as a pair of reals, denoted by  $(a|b)$
- We let  $(a|b) < (c|d)$  iff  $a < c$  or  $(a = c \text{ and } b < d)$ ; this defines a total order on composite numbers
- The point  $p = (p_x, p_y)$  becomes  $((p_x|p_y, (p_y|p_x)))$ . Then no two points have the same first or second coordinate
- The median x-coordinate or y-coordinate is a composite number

# Complexity analysis

12.

- The time complexity is primarily based on the number of intersections with the rectangular boundaries
- let the number be denoted by  $Q(n)$

## Complexity analysis

- $$Q(n) = \begin{cases} O(1) & \text{if } n = 1 \\ O(1) + 2Q(n/4) & \text{else.} \end{cases}$$

$$Q(n) = O(\sqrt{n})$$
- Similarly, we can generalize this to k dimensions
- $$Q(n) = \begin{cases} O(1) & \text{if } n = 1 \\ O(1) + 2^{k-1}Q(n/2^k) & \text{else.} \end{cases}$$

$$Q(n) = O(n^{1-1/k})$$

### derivation process

- Use the conclusions of the Master Theorem
- Use knowledge of sequences

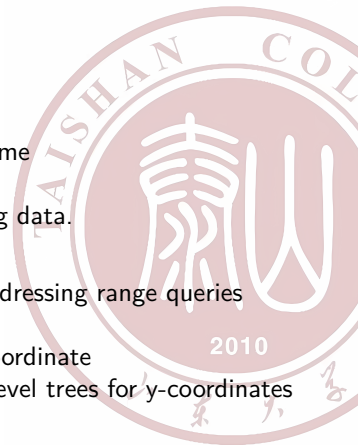

# Comparison

Data Structure	Complexity		
	Construction	Query	Space
KD Tree (2D)	$O(n \log n)$	$O(\sqrt{n})$	$O(n)$
KD Tree (kD)	$O(n \log n)$	$O(n^{1-1/k})$	$O(n)$
Range Tree (2D)	$O(n \log n)$	$O(\log^2 n)$	$O(n \log n)$
Range Tree (kD)	$O(n \log^{k-1} n)$	$O(\log^k n)$	$O(n \log^{k-1} n)$

# Comparison

- Similarities:
  - They can both address high-dimensional problems
  - They both employ a method of analyzing one dimension at a time
  - They require maintaining balance to ensure query efficiency
  - Typically, they are static and do not involve inserting or deleting data.
- Differences:
  - In contrast, the range tree appears to be more specialized in addressing range queries
  - K-D Tree is commonly used for nearest neighbor queries
  - K-D Tree: query path alternates between x-coordinate and y-coordinate
  - Range tree: first-level tree for x-coordinates and many second-level trees for y-coordinates

## ① Introduction

## ⑦ Application

# Application

- Database query  
Each type of information about an object can be abstracted into a dimension.
- Computational geometry
  - nearest neighbor query
  - interval intersection
  - quickly detect whether there is an intersection between two three-dimensional objects
